# Scientific Goals

Scientific Objectives	Observation Targets	Energy Range
CR Origin and Acceleration	Electron spectrum p - Fe individual spectra Ultra Heavy Ions ( $26 < Z \leq 40$ ) Gamma-rays (Diffuse + Point sources)	1 GeV - 20 TeV 10 GeV - 1000 TeV > 600 MeV/n 1 GeV - 1 TeV
Galactic CR Propagation	B/C and sub-Fe/Fe ratios	Up to some TeV/n
Nearby CR Sources	Electron spectrum	100 GeV - 20 TeV
Dark Matter	Signatures in electron/gamma-ray spectra	100 GeV - 20 TeV
Solar Physics	Electron flux	< 10 GeV
Gamma-ray Transients	Gamma-rays and X-rays	7keV - 20 MeV

Respond to the unresolved questions from the results found by recent observations

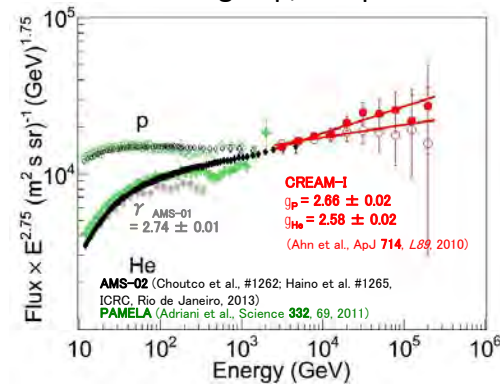

Increase of positron/electron ratio

Excess of electron+positron flux

Hardening of p, He spectra

# Energy Deposit Distribution of All Triggered Events by Observation for 597 days

## Distribution of deposit energies ( $\Delta E$ ) in TASC

The TASC energy measurements have successfully been carried out in the dynamic range of 1 GeV - 1 PeV.

## Performance of energy measurement in 1 GeV - 20 TeV

Energy resolution  
for electrons (TASC+IMC):  
< 3% over 10 GeV; < 2% over 100 GeV

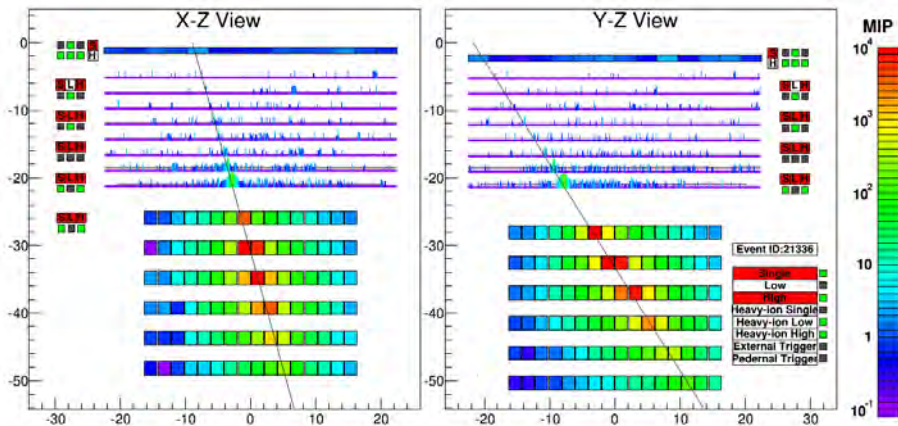

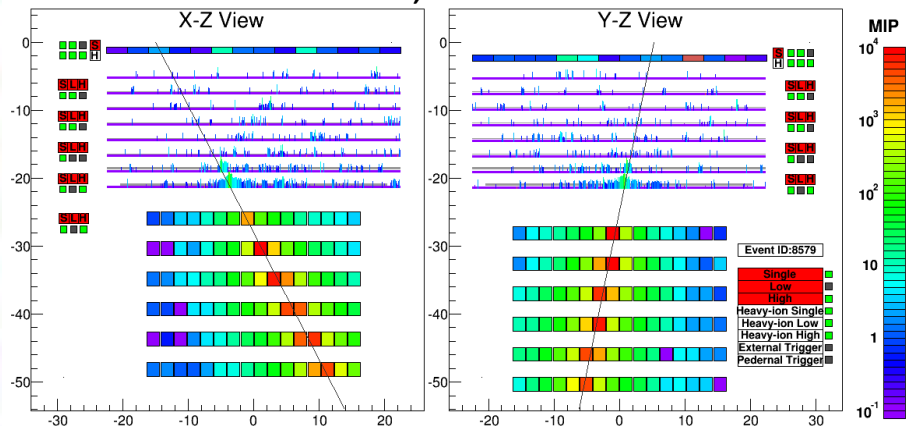

# Event Examples of High-Energy Showers

Electron,  $E=3.05$  TeV

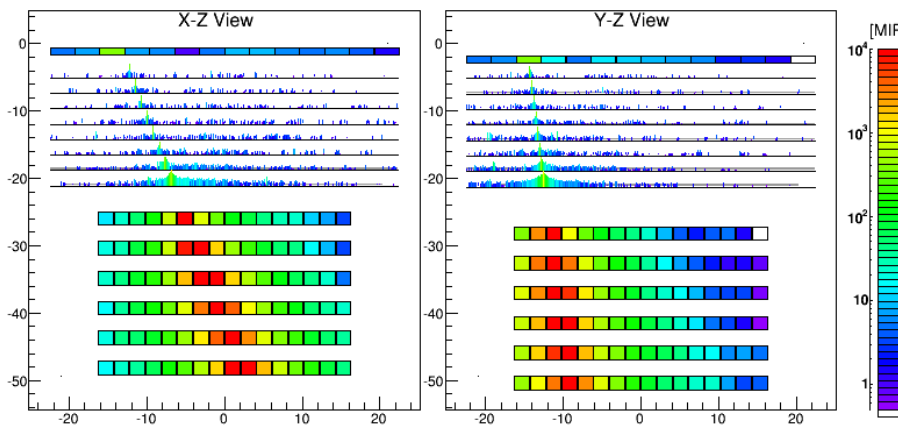

fully contained even at 3TeV

Proton,  $\Delta E=2.89$  TeV

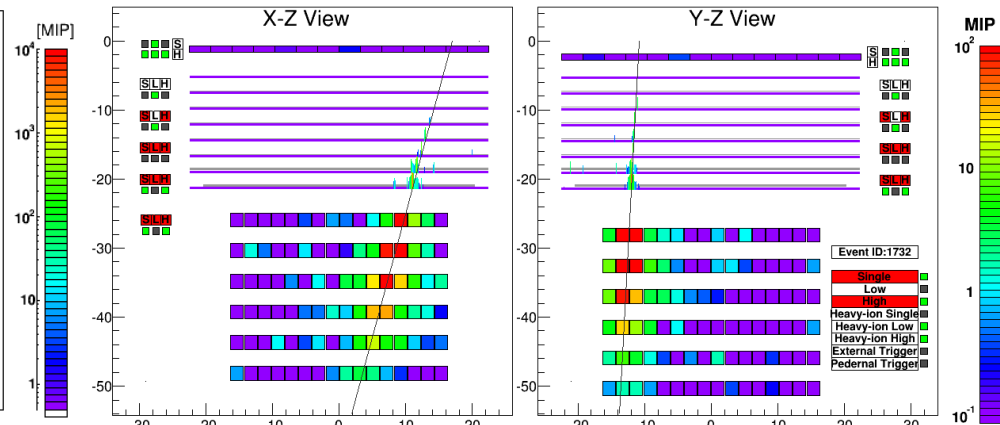

clear difference from electron shower

Fe( $Z=26$ ),  $\Delta E=9.3$  TeV

energy deposit in CHD consistent with Fe

Gamma-ray,  $E=44.3$  GeV

no energy deposit before pair production

# Preliminary Nuclei Measurements (p, He, $Z \leq 8$ )

P.S.Marrocchesi et al.,  
ICRC 2017, PoS 205.

CHD charge resolution (2 layers combined) vs. Z

Charge resolution combined CHD+IMC

Charge resolution using multiple dE/dx measurements from the IMC scintillating fibers

\*) Plots are truncated to clearly present the separation .

Non-linear response to  $Z^2$  is corrected  
both in CHD and IMC using a model.

A clear separation between p, He, up to  $Z=8$ ,  
can be seen from CHD+IMC data analysis.

## Preliminary proton flux $E^{2.7}$ from 50 GeV to 22 TeV

- 15 months of observation from December 1st, 2015 to February 28th, 2017
- subset of total acceptance: acceptance A (fiducial) with  $S\Omega = 416 \text{ cm}^2 \text{ sr}$
- Assessment of the systematic errors: **IN PROGRESS**

### Proton Event Selection

- 1) Fully-contained  
(Acceptance A) event in geometry
- 2) Good tracking (KF)
- 3) High Energy Trigger
- 4) Charge selection  $Z=1$
- 5) Helium rejection cuts
- 6) Electron rejection cuts

### Energy Unfolding using

an  $\mathcal{M}$    $\mathcal{M}^T$    $m$    $m$    $m$    $m$  from MC data

### (A) Fully-contained

Independent analysis is carried out for heavy nuclei in  $Z=8-26$ .

- ▣ Charge determination by CHD together with consistency requirement with IMC
- ▣ Consistent charge resolutions were obtained between the two analysis methods.

Charge distribution with CHD

Analysis Method (in particular for heavy nuclei)

- ▣ Unfolding procedure based on  applied with response function from MC data.
- ▣ Charge selection efficiencies and contaminations from neighboring charged nuclei are also taken into account in the unfolding procedure.

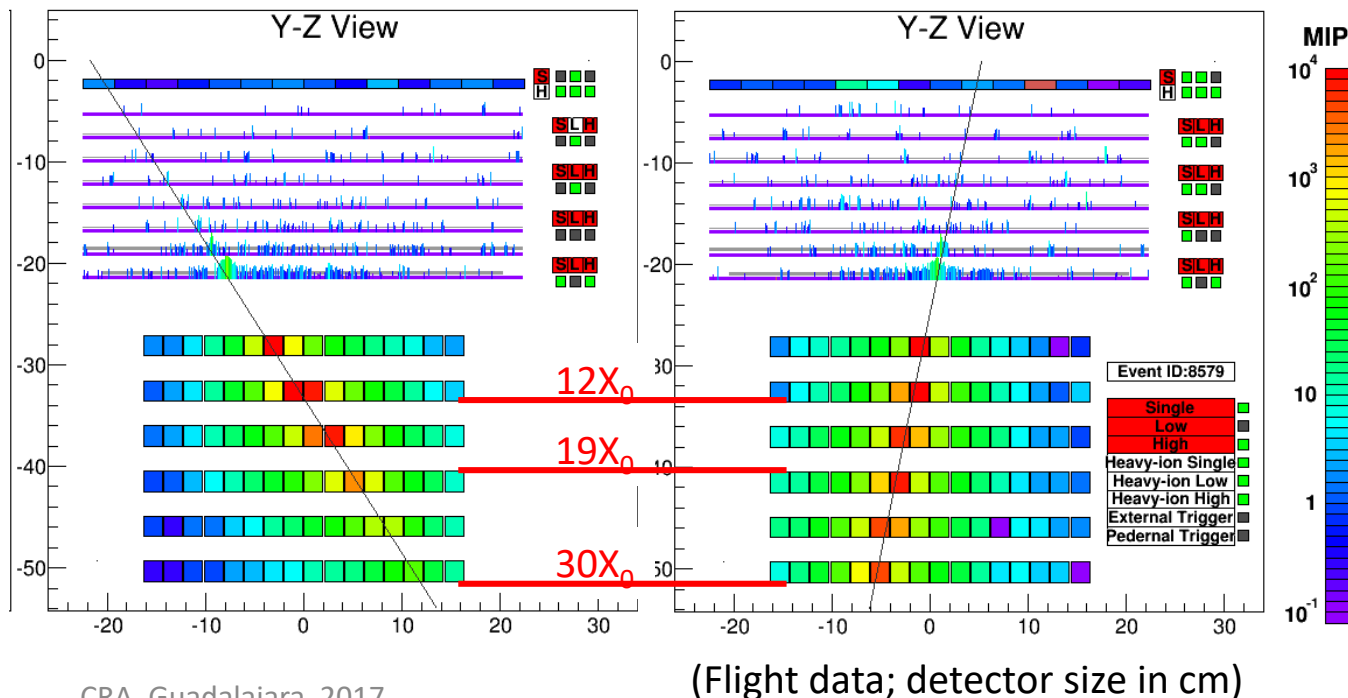

# All-Electron (electron + positron) Analysis

CALET is a dedicated detector for all-electron spectrum measurements.

⇒ CALET is best suited for observation of **possible fine structures** in the all-electron spectrum up to the trans-TeV region.

## 3TeV Electron Candidate

## Corresponding Proton Background

1. Reliable tracking  
well-developed  
shower core

2. Fine energy  
resolution  
full containment  
of TeV showers

3. High-efficiency  
electron ID  
 $30X_0$  thickness

# Electron Identification

## Simple Two Parameter Cut

$F_E$ : Energy fraction of the bottom layer sum to the whole energy deposit sum in TASC

$R_E$ : Lateral spread of energy deposit in TASC-X1

Separation Parameter K is defined as follows:

$$K = \log_{10}(F_E) + 0.5 R_E \text{ (/cm)}$$

## Boosted Decision Trees (BDT)

In addition to the two parameters in the left, TASC and IMC shower profile fits are used as discriminating variables.

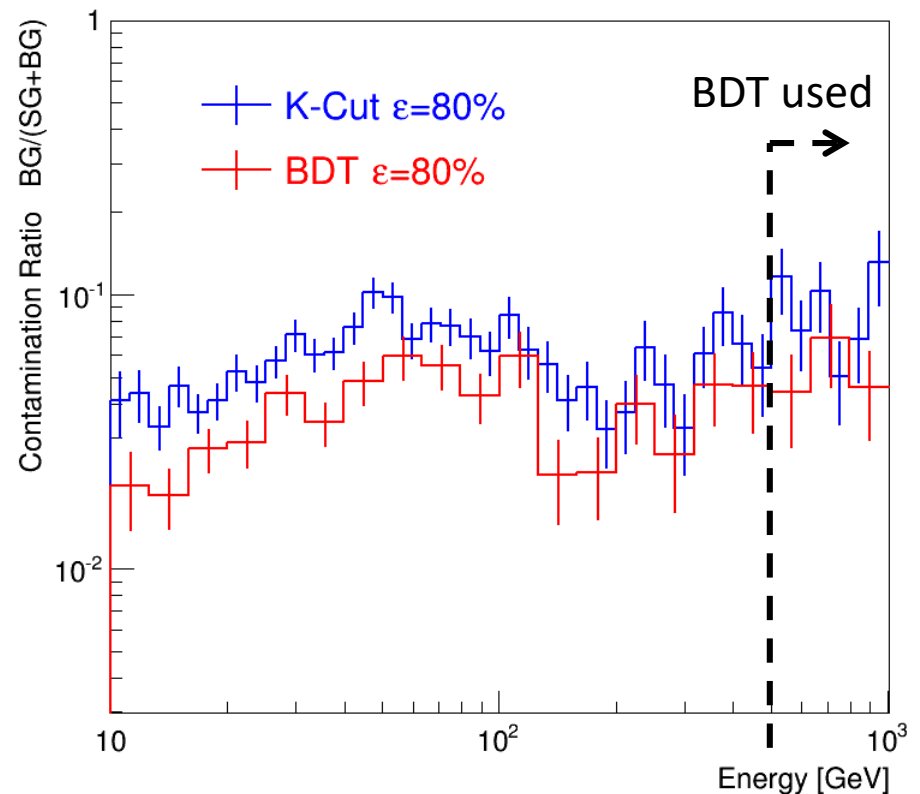

# Electron Efficiency and Subtraction of Proton Contamination

- Constant and high efficiency is the key point in our analysis.
- Simple two parameter cut is used in the low energy region while the difference in resultant spectrum are taken into account in the systematic uncertainty.

# All-Electron Energy Spectrum in 10 GeV ~ 1 TeV

- Geometry Condition:  $S\Omega = 570.3 \text{ cm}^2\text{sr}$  (55% for all acceptance)
- Live Time: 2015/10/13– 2017/03/31 ( $\times 0.84$ )  $\Rightarrow T = 3.89 \times 10^7 \text{ sec}$
- Exposure:  $S\Omega T = 2.24 \times 10^6 \text{ m}^2\text{sr sec}$   **$\sim 1/7$  of full analysis for 5 years**
- Absolute energy scale determined by geomagnetic cutoff energy.

## Nearby SNR and Anisotropy of the All-Electron Flux

- The Vela SNR could cause significant anisotropy in the TeV-region, depending on the cosmic-ray injection and propagation conditions
- With suitable conditions it is possible that the anisotropy signal occurs **only** at high energy, not detected by current measurements (Fermi-LAT)\*
- CALET can search for such signals due to good energy determination up to several TeV

## Analysis Method and Electron + Positron Event Sky Map

- Limits on anisotropy by finding the value of  $\delta$  for which the probability of the measured and smaller anisotropy is 5% (1-CL; CL=95%).
- Analysis method is based on M. Ackermann et al., Phys. Rev. D 82, 092003 (2010).

$$\delta = \frac{\Phi_{\max} - \Phi_{\min}}{\Phi_{\max} + \Phi_{\min}} ; P(\hat{\delta}, \delta) = \frac{3\sqrt{6}}{\sqrt{\pi}} \frac{\hat{\delta}^2}{\delta^3} e^{\left(-\frac{3\hat{\delta}^2}{2\delta^2}\right)} ; \int_0^{\delta_{\text{meas}}} P(\hat{\delta}, \delta) d\hat{\delta} = 1 - CL$$

- 627 days of flight data up to 170630.
- Full acceptance of 1040cm<sup>2</sup>sr (Preliminary)
- Electron identification by using BDT.

CALET Preliminary  
E>100GeV

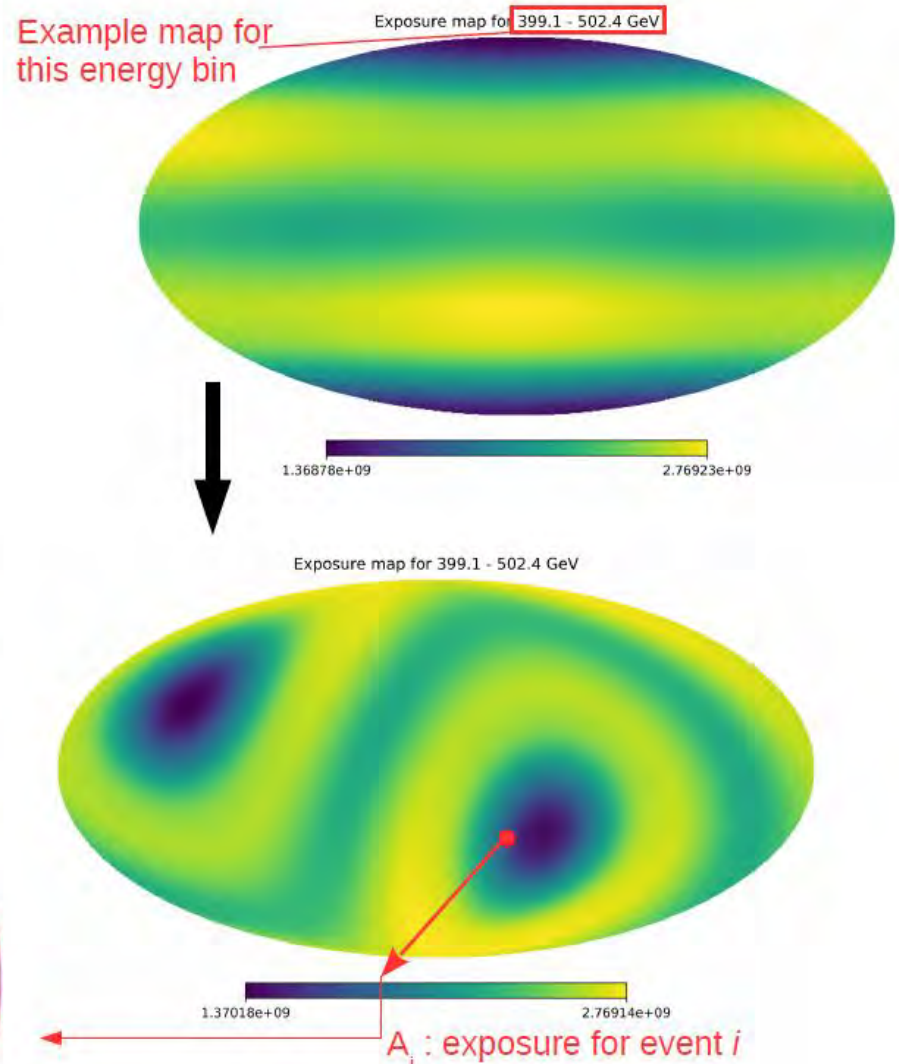

## Correction for Uneven Exposure

- ISS orbit convolved with CALET's energy and direction dependent effective area  $\rightarrow$  exposure in equatorial coordinates
- Converted to galactic coordinates
- Each event receives a weight which is the inverse of this energy and direction dependent exposure, normalized to the average exposure to the sky for the measured spectrum.

$w_i$  : weight for event  $i$

$$w_i = \frac{1}{A_i} \left( \frac{\sum_{events} \sum_{pixels} A(E, pixel)}{N_{events} N_{pixels}} \right)$$

## Results: Measured Anisotropy

$$\delta = \frac{\Phi_{\max} - \Phi_{\min}}{\Phi_{\max} + \Phi_{\min}}$$

Multipole expansion with  
*anafast* routines of *Healpix*:

$$\delta = \Phi_{\text{dipole}} / \Phi_{\text{monopole}}$$

Expected anisotropy  
(calculated by simulated  
uniform sky)

Measured anisotropy is  
much smaller than  
expected for this bin  
(1.4% prob.)

⇔ Need to consider  
trial factor

## Results: 95% Confidence Level Limit

$$P(\hat{\delta}, \delta) = \frac{3\sqrt{6}}{\sqrt{\pi}} \frac{\hat{\delta}^2}{\delta^3} e^{\left(-\frac{3}{2} \frac{\delta^2}{\hat{\delta}^2}\right)}$$

$$\int_0^{\delta_{\text{meas}}} P(\hat{\delta}, \delta) d\hat{\delta} = 1 - CL$$

Upper limit

Expected limit  
(calculated by simulated  
uniform sky)

Measured limit is even  
more uniform than  
expected value  
(1.4% prob.)

⇔ Need to consider  
trial factor

## Prospects:

1. Proving 1TeV region where significant limit can be set with more statistics
2. A dedicated search directed at the position of Vela (PoS, ICRC2017, 265)

# CALET $\gamma$ -ray Sky in LE ( $>1\text{GeV}$ ) Trigger

Exposure

Exposure is limited to low latitude region  
 $\Rightarrow |\text{declination}| > 60^\circ$  is hardly seen in LE gamma-ray trigger mode.

151013—170228  $E>1\text{GeV}$

Galactic Coordinate

Projection to Galactic Latitude

Galactic Diffuse Spectrum

contribution from point sources is not included in the model

# CALET $\gamma$ -ray Sky in HE ( $>10\text{GeV}$ ) Trigger

Exposure

Galactic Longitude

Galactic Latitude

+180°

HE trigger is always ON  
 $\Rightarrow$  Exposure is more uniform  
 than LE trigger.

151013—170228  $E>10\text{GeV}$

Galactic Coordinate

PRELIMINARY

Geminga:  
 $\sim 10$   
 Crab:  
 $\sim 20$   
 Vela:  
 $\sim 20$

**Vela, Crab and Geminga are identified.**

Galactic Longitude

Projection to Galactic Latitude

Diffuse Spectrum

contribution from point sources is not included in the model

# CALET UPPER LIMITS ON X-RAY AND GAMMA-RAY COUNT RATES OF GW 151226

Astrophysical Journal Letters 829:L20(5pp), 2016 September 20

The CGBM covered 32.5% and 49.1% of the GW 151226 sky localization probability in the 7 keV – 1 MeV and 40 keV – 20 MeV bands respectively. We place a 90% upper limit of  $2 \times 10^{-7} \text{ erg cm}^{-2} \text{ s}^{-1}$  in the 1 – 100 GeV band where CAL reaches 15% of the integrated LIGO probability ( $\sim 1.1 \text{ sr}$ ). The CGBM  $7\sigma$  upper limits are  $1.0 \times 10^{-6} \text{ erg cm}^{-2} \text{ s}^{-1}$  (7–500 keV) and  $1.8 \times 10^{-6} \text{ erg cm}^{-2} \text{ s}^{-1}$  (50–1000 keV) for one second exposure. Those upper limits correspond to the luminosity of  $3\text{--}5 \times 10^{49} \text{ erg s}^{-1}$  which is significantly lower than typical short GRBs.

CGBM light curve at a moment of the GW151226 event

Figure 1. The CGBM light curves in 0.125 s time resolution for the high-gain data (left) and the low-gain data (right). The time is offset from the LIGO trigger time of GW 151226. The dashed-lines correspond to the 5  $\sigma$  level from the mean count rate using the data of  $\pm 10 \text{ s}$ .

Upper limit for gamma-ray burst monitors and Calorimeter

HXM: 7–500 keV

SGM: 50–1000 keV

Figure 2. The sky maps of the  $7\sigma$  upper limit for HXM (left) and SGM (right). The assumed spectrum for estimating the upper limit is a typical BATSE S-GRBs (see text for details). The energy bands are 7–500 keV for HXM and 50–1000 keV for SGM. The GW 151226 probability map is shown in green contours. The shadow of ISS is shown in black hatches.

Calorimeter: 1–100 GeV

Figure 3. The sky map of the 90% upper limit for CAL in the 1–100 GeV band. A power-law model with a photon index of  $-1$  is used to calculate the upper limit. The GW 151226 probability map is shown in green contours.

# Summary and Future Prospects

- ❑ CALET was successfully launched on Aug. 19, 2015, and the detector is being very stable for observation since Oct. 13, 2015.
- ❑ As of Jun.30, 2017, total observation time is 627 days with live time fraction to total time to close 84%. Nearly 409 million events are collected with high energy (>10 GeV) trigger.
- ❑ Careful calibrations have been adopted by using “MIP” signals of the non-interacting p & He events, and the linearity in the energy measurements up to  $10^6$  MIPs is established by using observed events.
- ❑ Preliminary analysis of nuclei, all electrons and gamma-rays have successfully been carried out to obtain the energy spectra in the energy range;  
Protons: 55 GeV~22 TeV, Ne-Fe: 500 GeV~70 TeV, All electrons: 10 GeV~1 TeV.
- ❑ Preliminary analysis of electron anisotropy is presented.
- ❑ CALET's CGBM detected nearly 60 GRBs (~20 % short GRB among them ) per year in the energy range of 7keV-20 MeV, as expected. Follow-up observation of the GW events is carried out. ( Not reported in this talk)
- ❑ The so far excellent performance of CALET and the outstanding quality of the data suggest that a 5-year observation period is likely to provide a wealth of new interesting results.
